BLOCK COPOLYMERS CONTAINING POLY(1,3-CONJUGATED
DIENES) AND POLY(VINYLPHENOLS), SILYL PROTECTED
POLY(VINYLPHENOLS) OR POLY(METAL PHENOLATES)

Abstract of the Disclosure

5 Diblock and triblock copolymers are disclosed consisting of a poly(1,3-conjugated diene) block and a block of a poly(vinylphenol), a silyl protected poly(vinylphenol), or a poly(metal phenolate).

BLOCK COPOLYMERS CONTAINING POLY(1,3-CONJUGATED DIENES) AND POLY(VINYLPHENOLS), SILYL PROTECTED POLY(VINYLPHENOLS) OR POLY(METAL PHENOLATES)

Background of the Invention

5 Homopolymers and copolymers of poly(vinylphenols) are being utilized for many new technological applications. Recent interest in poly(vinylphenols) has focused in the areas of photoresists for microlithography, adsorbants for the
10 removal of organic compounds from aqueous wastes, and biomedical applications. Further applications, particularly in the field of polymer blends, include electrical insulators, fire retardant materials and permselective membranes.

15 However, due to the inherent reactivity of phenols, vinylphenol polymerizes poorly when free radical or cationic initiators are utilized, and not at all with anionic initiators. Chain transfer to monomer and/or polymer is believed to be partly
20 responsible for the low molecular weights which are usually obtained by free radical polymerization of vinylphenol. Moreover, it has been demonstrated that pure 4-vinylphenol undergoes self-initiated polymerization and the degree of polymerization is
25 essentially independent of added free radical initiator. Thus, in order to obtain high molecular weight linear polymers, a protected phenol must be polymerized and subsequently deblocked.

The synthesis of poly(vinylphenol)-
30 containing block copolymers has received limited attention compared to homopolymers and random copolymers of poly(vinylphenol) due to the inherent difficulties in preparing block copolymers and the lack of available synthetic routes and suitable
35 protected monomers for making block polymers.

Thermoplastic elastomers based on block copolymers of styrene and an aliphatic, conjugated

1,3-diene are being used with increasing frequency for many applications. Their desirable properties arise from the ability of the chemically different blocks to microphase separate resulting in a 5 thermally processable elastomer. The use temperatures for the elastomer are governed by the glass transition temperatures of the blocks, i.e. 100°C and -60°C for the polystyrene block and polyisoprene blocks respectively. In addition, the 10 ability of the blocks to microphase separate depends on the difference in solubility of the two blocks. Limited attention has been directed towards maximizing the difference in solubility by increasing the polarity of the styrenic block. Further, 15 increasing the upper glass transition temperature and introducing reactive, polar functionalities to the styrenic blocks have been relatively unexplored.

Thus, it is evident that it would be desirable to provide new classes of poly(vinylphenol) 20 block copolymers. It would be particularly desirable to provide new classes of poly(vinylphenol) block copolymers by anionic polymerization because this technique provides polymers having narrow molecular weight distributions and predictable molecular 25 weights.

Summary of the Invention

We have discovered that block copolymers can be prepared containing repeating units of a poly(1,3-conjugated diene) and units of a poly(vinylphenol), a 30 silyl protected poly(vinylphenol) or a poly(metal phenolate).

More particularly, in accordance with this invention, there are provided block copolymers consisting of at least one poly(1,3-conjugated diene) 35 block and at least one block of a poly(vinylphenol), a silyl protected poly(vinylphenol), or a poly(metal phenolate).

-3-

- In another aspect of this invention, the above-described block copolymers are prepared in a method which comprises forming the diene block by polymerizing a polymerizable 1,3-conjugated diene
- 5 monomer in a reaction medium comprising a nonpolar solvent and an anionic initiator; forming the silyl protected poly(vinylphenol) block by adding to the medium and polymerizing therein a polymerizable silyl protected vinylphenol monomer; optionally removing
- 10 said silyl protective group; optionally contacting the unprotected polymer with a basic metal salt; and isolating the resulting block copolymer.

Alternatively, the silyl protected phenol block can be formed first in a nonpolar medium,

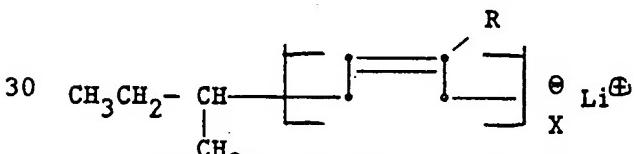

15 followed by the formation of the rubbery diene block. Optional deprotection to the phenol or conversion to the metal phenolate as described above is possible.

It is a particularly advantageous feature of

20 this invention that there are provided new classes of block copolymers and a method for the preparation thereof, which block copolymers possess narrow molecular weight distributions and predictable molecular weights.

25 Detailed Description of Preferred Embodiments

This invention is based at least partly on the discovery that a polymeric initiator such as

initiates the polymerization of a silyl protected vinylphenol monomer under conditions in which the anionic portion of the silyl protected

35 poly(vinylphenol) does not react with the silyl moiety thereof to an extent which prohibits polymerization.

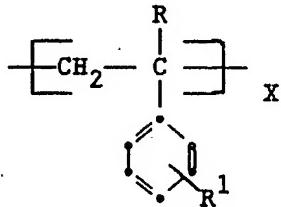

-4-

This invention provides block copolymers having the configuration AB. Although the description which follows is concerned primarily with block copolymers in a diblock configuration, the 5 block copolymers of this invention can exist as ABA triblocks and higher order block copolymers. Conventional coupling agents such as dichlorosilanes and divinylbenzene can be used to prepare ABA triblock structures.

10 As noted, the block copolymers of this invention contain at least one block of a poly(vinylphenol), a silyl protected poly(vinylphenol), or a poly(metal phenolate). These blocks preferably have the structural formula:

15

20

wherein R is H or CH₃;

R¹ is selected from the group consisting of -OH, -OSi(CH₃)₂C(CH₃)₃ and -OM;

25 M is a metal cation; and

X is 3 - 100,000. In preferred embodiments, X is 10-10,000. The molecular weight of the A block can vary from about 4 x 10²-12 x 10⁶ and preferably is from 12 x 10² - 12 x 10⁵.

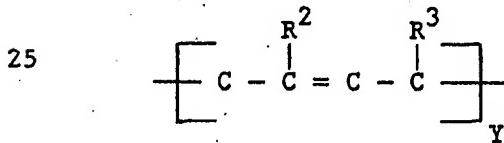

30 The methods described hereinafter can also be used to prepare compositions of matter containing a linear 1,3-conjugated diene polymer having attached thereto one or two units derived from the above-described structural formula, i.e., wherein X 35 is one or 2. Such telechelic compositions find utility, for example, as macromonomers in a

subsequent polymerization or as difunctional monomers useful in step growth polymerization.

In the above formula, M represents a metallic cation. M can be essentially any univalent or divalent alkali, alkaline earth or transition metal cation. Non-limiting examples of such cations include sodium, magnesium, calcium, lithium, potassium and zinc cations.

It is contemplated that R¹ in the formula above can be located in either the para- or meta-position. It is preferred, primarily for reasons of availability of starting materials and ease of synthesis, that R¹ be located in the para-position. Additionally, it is contemplated that in addition to the R¹ substituent that the pendant benzene ring can be substituted with such non-interfering substituents as C₁-C₄ alkyl, e.g., in one or both meta positions.

The rubbery diene block is derived from a 1,3-conjugated diene such as 1,3-butadiene, isoprene or 1,3-pentadiene. This block preferably has the structural formula

wherein R² and R³ are individually H or CH₃ and Y is 3-100,000. In preferred embodiments, Y is 30 10-10,000. The molecular weight of the diene block can be varied from about 1.5 x 10²- 5 x 10⁶ and preferably is from 5 x 10²- 5 x 10⁵.

Higher molecular weights than those described above are generally not preferred due to 35 problems with trace impurities and control of the polymerization reactions.

The block copolymers of this invention can be prepared preferably in accordance with the methods described in the summary above. As noted, the diene block can be formed by polymerizing a polymerizable

- 5 1,3-conjugated diene monomer in a reaction medium including a nonpolar solvent and an initiator. Preferably, the diene block can be formed in cyclohexane at a temperature from 10-70°C, more preferably 15-60°C. Cyclohexane permits generation
10 of the desired 1,4-microstructure. On the other hand, polar solvents, such as, for example, THF, or polar modifiers, such as, for example, dipiperidinoethane, provide a structure having pendant unsaturation (3,4-microstructure). However,
15 other nonpolar solvents such as acyclic aliphatic hydrocarbon compounds and toluene are expected to be useful in forming the desired poly(1,3-diene) block structure.

After the diene block is formed, the
20 protected phenol block is formed by adding to the reaction medium and polymerizing therein the silyl protected vinylphenol monomer.

Alternatively, the protected phenol block can be formed first by, for example, polymerizing the
25 silyl protected vinylphenol monomer in a reaction medium including a nonpolar solvent and an initiator. Preferably, the protected phenol block can be formed in cyclohexane at a temperature from 10-70°C, more preferably 15-60°C. Then the diene
30 block is formed by adding to the reaction medium and polymerizing therein the 1,3-conjugated diene monomer. Under these conditions, it was surprising that the carbanion intermediate of the first block was sufficiently long-lived to provide block
35 copolymers upon addition of the diene.

A schematic of a preferred preparation sequence follows.

- As depicted in the above scheme, the preferred silyl protected starting monomer is 4-(tert-butyldimethylsiloxy)styrene. This starting monomer itself can be readily prepared by treating 5 4-vinylphenol with tert-butyldimethylsilyl chloride in the presence of triethyl amine in dichloromethane or by other conventional methods familiar to those skilled in the art.

While 4-(tert-butyldimethyl)silyl is the 10 preferred protecting group, other sterically hindered trialkyl and/or aryl substituted silyl protecting groups, for example, triisopropylsilyl and triisobutylsilyl groups, are expected to be useful herein. On the other hand, trimethyl silyl is not an 15 effective protecting group. It is believed that the reason for this is that such group provides insufficient steric hindrance.

Suitable initiators for the polymerization 20 of polymers in accordance with this invention include organolithium compounds such as n-butyllithium, sec-butyllithium, tert-butyllithium, n-hexyllithium, iso-hexyllithium, phenyllithium, naphthyllithium, sodium alpha-methylstyrene dimers, organometallic 25 compounds of group 1A of the Periodic Table such as sodium naphthalide and lithium naphthalide and organomagnesium compounds. The molar ratio of the monomer to the initiator selected depends on the molecular weight desired. The molar ratio of monomer to initiator can range from about 5 to about 10^5 . 30 The polymerization reactions can be terminated by adding a terminator such as methanol to the reaction medium.

S. Nakahama, "Anionic Living Polymerization 35 of Protected Functional Monomers" A.C.S. Polymer Preprints 27, No. 1 (1986) pages 194-195 describes the preparation of a block copolymer of

poly(vinylphenol) and poly(α -methylstyrene) in THF at -78°C. However, there is no suggestion of applicants' block copolymers containing diene units with predominantly 1,4-microstructure. Moreover, it was surprising that applicants' copolymers could be prepared in light of competing reactions which one skilled in the art would expect to predominate under the reaction conditions required to prepare these block copolymers. For example, it was not obvious that the polymeric initiator described above would initiate polymerization of the silyl protected vinylphenol monomer without preferentially attacking the reactive silicon group. Furthermore, it was unexpected that the anionic portion of the silyl protected poly(vinylphenol) intermediate did not react with the reactive silyl moiety at an appreciable rate under the preferred reaction conditions, i.e., in the presence of a nonpolar solvent, e.g., cyclohexane. Finally, Nakahama et al suggest that low temperature, i.e., -78°C, is critical to the stability of the poly[4-(tert-butyldimethylsiloxy)styryl]lithium intermediate. Thus, it was surprising that this intermediate was sufficiently stable at temperatures of 15-60°C to enable the formation of well-defined block copolymers.

Removal of the protective groups can be accomplished by acid hydrolysis of the polymer containing protected hydroxyl groups. For example, the protected polymer can be converted to its hydroxyl form substantially quantitatively by hydrolysis in an HCl-dioxane solution. Other known techniques are expected to be useful in removal of the protective group, e.g., tetrabutyl ammonium fluoride.

The block copolymer containing the poly(metal phenolates) can be conveniently prepared by removing the silyl protective group as described

above and contacting the block copolymer with an appropriate basic metal salt. Thereafter, the block copolymers of the invention can be isolated by conventional techniques.

- 5 Polymers of this invention include:
poly(vinylphenol-b-isoprene),
poly(vinylphenol-b-(1,3-butadiene)),
poly(vinylphenol-b-(1,3-pentadiene)),
poly(4-tert-butyldimethylsiloxyxystyrene-b-isoprene),
10 poly(4-tert-butyldimethylsiloxyxystyrene-b-(1,3-
butadiene))
poly(4-tert-butyldimethylsiloxyxystyrene-b-(1,3-penta-
diene)) and
poly(potassium phenolate-b-isoprene).

- 15 The block copolymers of this invention are useful as low modulus thermoplastic elastomeric rubbers and as components in polymer blends. In addition, these block copolymers are expected to be useful as flow and viscosity modifiers, and in
20 adhesive and surfactant compositions.

- As noted above, it is a particularly advantageous feature of this invention that the described block copolymers can be readily prepared in predictable molecular weights having a narrow
25 molecular weight distribution.

- The block copolymers of this invention containing poly(vinylphenol) have several advantages over block copolymers containing styrene and alkyl-substituted styrene analogues. For example, the
30 poly(vinylphenol) block renders the copolymer more hydrophilic and introduces hydrogen bonding capabilities. Further, the poly(vinylphenol) has a thermal stability comparable to styrene and has a glass transition temperature of about 185°C which is
35 approximately 80°C higher than styrene. In addition, the phenolic moiety can be utilized in subsequent reactions which are characteristic of monomeric phenols.

-11-

It is contemplated that the blocks containing repeating units derived from the 1,3-conjugated diene monomer can be hydrogenated by techniques known in the art to form polyethylene and 5 poly(ethylene-co-propylene) blocks.

The following examples further illustrate this invention.

Example 1:

Approximately 20 g of 4-(tert-butyldimethylsiloxy)styrene was dissolved in 400 mL of cyclohexane at 60°C under an inert atmosphere. The monomer had been previously vacuum distilled from calcium hydride and dibutylmagnesium. Cyclohexane was purified by stirring over sulfuric acid for 8-10 days and 10 distilling from a sodium dispersion under nitrogen. s-Butyllithium initiator (1.3 M in cyclohexane, 1.54 mL) was added to the reactor and immediately an orange color which was consistent with a delocalized carbanion formed. The reactor nitrogen pressure was 15 maintained at 10-15 psi during the course of the polymerization. After polymerization of the first block, isoprene (44 mL) was added directly to the reactor and the orange color faded to a pale yellow color which is consistent with the formation of 20 poly(isoprenyllithium) anion. The second block was allowed to polymerize for 2 hours and degassed methanol was used to terminate the polymerization. The polymer was precipitated into a 10X excess of 25 methanol and dried in vacuo at 30°C. Antioxidant (0.5 wt. %) was added to prevent oxidative degradation.

Example 2:

The monomers and solvent were purified exactly as described in Example 1. However, in this 35 example the order of monomer addition was reversed and similar color changes were noted. Isoprene was

-12-

- initiated with s-butyllithium in cyclohexane and allowed to polymerize for 2 hours at 60°C. 4-(tert-Butyldimethylsiloxy)styrene was added directly to the poly(isoprenyllithium) carbanion. The polymer was
- 5 terminated and isolated in a similar fashion. The molecular weight distributions of resulting block copolymers prepared by this technique ranged from about 1.15 to about 1.7. ^1H NMR analysis indicated efficient incorporation of the silyl protected
- 10 monomer.

Example 3:

- Approximately 30 g of isoprene was dissolved in 400 mL of cyclohexane and initiated with 0.77 mL (1.3 M in cyclohexane) of s-butyllithium at 60°C.
- 15 The polymerization was allowed to proceed for 2 hours to ensure complete conversion. Tetrahydrofuran (300 mL) which had been vacuum distilled twice from sodium/benzophenone was added to the reactor. Several aliquots were transferred to round bottomed flasks
- 20 and cooled to -78°C. 4-(tert-Butyldimethylsiloxy)-styrene was added via a syringe to the round bottomed flasks and an orange color which was indicative of the formation of a delocalized carbanion was formed. After 1 hour, the polymerization was terminated with
- 25 degassed methanol and isolated in a similar fashion. The molecular weight distributions of resulting block copolymers prepared by this technique ranged from about 1.15 to about 1.7. ^1H NMR analysis indicated efficient incorporation of the silyl protected
- 30 monomer.

Example 4:

- 20 g 4-(tert-Butyldimethylsiloxy)styrene was dissolved in 300 mL of cyclohexane at 60°C and initiated with 3.05 mL of s-butyllithium (1.3 M in
- 35 cyclohexane). Molecular weight measurements by gel permeation chromatography indicated that

polymerization was complete after 30 minutes and that molecular weight distributions ranged from about 1.2 to about 1.7.

Example 5:

- 5 In a three-necked, round-bottomed flask fitted with a reflux condenser and gas inlet adaptor, 3.75 g of poly(isoprene-b-t-buylidimethylsiloxy styrene) and 0.4 g of Irganox TM an antioxidant, were dissolved in 40 mL of p-dioxane. Sufficient conc HCl
- 10 to make a saturated solution (ca. 5 mL) was added dropwise with efficient stirring. After nitrogen had been bubbled through the solution for approximately 10 min, the mixture was stirred and heated at 50°C for approximately 8 hrs. Then the mixture was
- 15 precipitated into 800 mL of heptane, filtered, and the precipitate washed well with heptane, and dried in a vacuum dessicator for 48 hrs. Peaks in the proton nmr spectrum at 7.3 and 6.5 ppm δ, and the absence of peaks at 1.0 and 0.15 ppm, confirmed the
- 20 complete removal of siloxy protecting group. The peaks at 5.1 (broad s), 4.8 (pair of doublets), 2.1, 1.7, and 1.6 ppm (all singlets) integrated the same as those in the protected block copolymer and are consistent with a mostly (> 90%) 1,4 microstructure
- 25 of the poly(isoprene) blocks. There was no evidence of new peaks in the nmr spectrum resulting from degradation of the isoprene blocks. Differential Scanning Calorimetry (DSC) revealed two glass transition temperatures, -57°C and 185°C, consistent
- 30 with a microphase separated block copolymer of isoprene and 4-vinylphenol.

Example 6:

- 35 In a 125 mL Erlenmeyer flask, 4.0 g of the protected block copolymer of Example 5 was dissolved in 60 mL of THF under argon. 10 mL of glacial acetic acid was added dropwise with rapid stirring, followed

-14-

by a sufficient volume of 1.0 M tetrabutylammonium fluoride solution in THF to provide a stoichiometric excess with respect to the number of moles of t-butyldimethylsiloxy protecting group. This
5 solution was stirred under Ar for 4 hours at room temperature, then precipitated into 1 L of heptane, filtered, the precipitate washed well with heptane and then dried in a vacuum dessicator at room
10 temperature for at least 24 hours. Characterization produced results as described in Example 5.

The invention has been described in detail with particular reference to certain preferred embodiments thereof, but it will be understood that variations and modifications can be effected within
15 the spirit and scope of the invention.

20

25

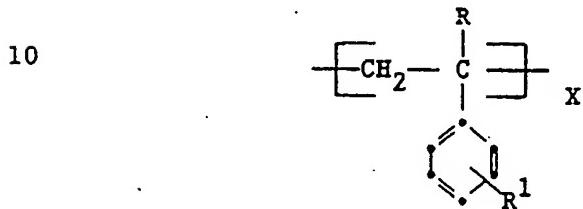

30

35

-15-

What is claimed is:

1. A block copolymer containing at least one poly(1,3-conjugated diene) block and at least one block of a poly(vinylphenol), a silyl protected 5 poly(vinylphenol) or a poly(metal phenolate).
2. The copolymer of claim 1 containing a block of repeating units having the structural formula

15 wherein R is H or CH₃:

R¹ is selected from the group consisting of -OH, -OSi(CH₃)₂C(CH₃)₃ and -OM; M is a metal cation; and X is 3 - 100,000.

20 3. The copolymer of claim 1 containing a poly(vinylphenol) block.

4. The copolymer of claim 1 containing a silyl protected poly(vinylphenol) block.

5. The copolymer of claim 1 containing a 25 poly(metal phenolate) block.

6. The copolymer of claim 4 containing a poly(4-tertbutyldimethylsiloxy styrene) block.

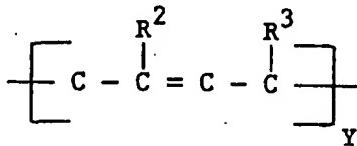

7. The copolymer of claim 2 wherein R¹ is located in the para- or meta- position.

30 8. The copolymer of claim 2 wherein X is 10-10,000.

-16-

9. The copolymer of claim 1 wherein said diene block contains repeating units having the structural formula:

5

10 wherein R² and R³ are individually H or CH₃ and Y is 3-100,000.

10. The copolymer of claim 1 wherein said diene block contains repeating units derived from isoprene, 1,3-butadiene or 1,3-pentadiene.

11. The copolymer of claim 9 wherein Y is 15 10-10,000.

12. A method of preparing the block copolymer of claim 1, said method comprising the steps of:

20 forming a poly(1,3-conjugated diene) block by polymerizing a polymerizable 1,3-conjugated diene monomer in a reaction medium comprising a nonpolar solvent and an anionic initiator;

25 forming a silyl protected poly(vinylphenol) block by adding to said reaction medium and polymerizing therein a polymerizable silyl protected vinylphenol monomer;

optionally removing said silyl protective group;

30 optionally contacting the unprotected polymer with a basic metal salt; and isolating the block copolymer.

13. The method of claim 12, wherein said nonpolar solvent is cyclohexane.

35 14. The method of claim 13 wherein said blocks are formed at a temperature from 10-70°C.

-17-

15. A method of preparing the block copolymer of claim 1, said method comprising the steps of:

forming a silyl protected poly(vinylphenol).

5 block by polymerizing a polymerizable silyl protected monomer in a reaction medium comprising a nonpolar solvent and an anionic initiator;

10 forming a poly(1,3-conjugated diene) block by adding to said reaction medium and polymerizing therein a polymerizable 1,3-conjugated diene monomer;

optionally removing said silyl protective group;

optionally contacting the unprotected polymer with a basic metal salt; and

15 isolating said block copolymer.

16. The method of claim 15, wherein said nonpolar solvent is cyclohexane.

17. The method of claim 16 wherein said blocks are formed at a temperature from 10-70°C.

20 18. A method of preparing a composition of matter containing a linear 1,3-conjugated diene polymer having attached thereto one or two units derived from a vinylphenol, a silyl protected vinylphenol or a metal phenolate, said method comprising the steps of:

forming a linear 1,3-conjugated diene polymer by polymerizing a polymerizable 1,3-conjugated diene monomer in a reaction medium comprising a nonpolar solvent and an anionic

25 initiator;

30 adding a silyl protected vinylphenol monomer to said reaction medium;

optionally removing said silyl protective group;

35

-18-

optionally contacting the unprotected composition with a basic metal salt; and isolating the composition of matter.

19. A method of preparing a composition of
- 5 matter containing a linear 1,3-conjugated diene polymer having attached thereto one or two units derived from a vinylphenol, a silyl protected vinylphenol or a metal phenolate, said method comprising the steps of:
- 10 adding a silyl protected vinylphenol monomer to a reaction medium comprising a nonpolar solvent and an anionic initiator;
- forming a linear 1,3-conjugated diene polymer by polymerizing a polymerizable
- 15 1,3-conjugated diene monomer in said reaction medium; optionally removing said silyl protective group;
- optionally contacting the unprotected composition with a basic metal salt; and
- 20 isolating the composition of matter.
